Marco Pistore

Marco Roveri

# Part I: Basic of NuSMV and SMV language

---

# An Overview of NuSMV

---

- NuSMV is an OBDD-based symbolic model checker.
- Uses a structured language to describe finite-state systems.
- It is oriented to the verification of synchronous systems.
- Allows to model check CTL and LTL specifications.
- When the specification is not satisfied, it produces a counterexample.
- Allows to simulate the specified model.

# An Overview of NuSMV

---

- NuSMV is a reengineering/reimplementation and extension of SMV [McM93].
- SMV was developed by K. McMillan at CMU. It was the first symbolic model checker.
- NuSMV is the result of a joint project between CMU and ITC-IRST involving A. Cimatti, E. Clarke, F. Giunchiglia, A. Morichetti, M. Roveri.
- NuSMV is under ongoing development.
- NuSMV is available at the URL:

`http://afrodite.itc.it:1024/~nusmv`

# The first SMV program

---

```
MODULE main
VAR
  b0 : boolean;

ASSIGN
  init(b0) := 0;
  next(b0) := !b0;
```

# Declaring state variables

---

The SMV language provides booleans, enumerative and bounded integers as data types:

## **boolean:**

```
VAR
  x : boolean;
```

## **enumerative:**

```
VAR
  st : {ready, busy, waiting, stopped};
```

## **integers (bounded):**

```
VAR
  n : 1..8;
```

## Adding a state variable

```

MODULE main
  VAR
    b0 : boolean;
    b1 : boolean;

  ASSIGN
    init(b0) := 0;
    next(b0) := !b0;
  
```

### Remarks

- ☞ The new state space is the cartesian product of the ranges of the variables.
- ☞ Synchronous composition between the “subsystems” for b0 and b1.

## Declaring the set of initial states

---

- ➔ For each variable, we constrain the values that it can assume in the initial states.

```
init(<variable>) := <simple_expression> ;
```

- ➔ `<simple_expression>` must evaluate to values in the domain of `<variable>`.
- ➔ If the initial values for a variable are not specified, then they can be any in the domain of the variable.

## Declaring the set of initial states

---

```
MODULE main
VAR
  b0 : boolean;
  b1 : boolean;

ASSIGN
  init(b0) := 0;
  next(b0) := !b0;

  init(b1) := 0;
```

# Expressions

---

- ➡ Expressions in SMV do not necessarily evaluate to one value.
- ➡ They can represent several possible values.
- ➡ Alternatively, we can say that an expression evaluates to a set of values, from which one may be chosen.
- ➡ A constant  $c$  is considered as a syntactic abbreviation for  $\{c\}$  (the singleton containing  $c$ ).
- ➡ The meaning of  $:=$  in assignments is that the lhs can assume non deterministically a value in the set the rhs evaluate to.

```
init(x) := {1, 2, 3};
```

## Expression (cont.)

➔ Arithmetic operators:

+   -   \*   / (integer division)   mod   - (unary)

➔ Comparison operators:

=   >   <   <=   >=

➔ Logic operators:

&   |   ! (unary, logical not)   ->   <->

➔ Set operators:

in (set inclusion)   union (set union)

➔ Conditional expression:

```
case
  e1 : e2;
  e3 : e4;
  ...
esac
```

if e1 then e2 else if e3 then e4 else ...

## Declaring the transition relation

---

- ➔ The transition relation is specified by constraining the values that variables can assume in the next state.

```
next (<variable>) := <next_expression> ;
```

- ➔ `<next_expression>` depends on “current” and “next” variables;
- ➔ it must evaluate to values in the domain of `<variable>`.
- ➔ If no `next ()` assignment is specified for a variable, then the variable can evolve non deterministically, i.e. it is unconstrained.
- ➔ Unconstrained variables can be used to model non-deterministic inputs to the system.

## Declaring the transition relation

```

MODULE main
VAR
  b0 : boolean;
  b1 : boolean;

ASSIGN
  init(b0) := 0;
  next(b0) := !b0;

  init(b1) := 0;
  next(b1) := ((!b0 & b1) | (b0 & !b1));

```

## Specifying normal assignments

---

- ➡ Normal assignments constrain the current value of a variable to the value of other current variables.
- ➡ They can be used to model outputs of the form  $O(\underline{y}, \underline{x})$ , where  $\underline{y}$  is the vector of output variables, and  $\underline{x}$  is the vector of state variables.
- ➡ Normal assignments have the following form:

`<variable> := <simple_expression> ;`

- ➡ `<simple_expression>` must evaluate to values in the domain of the `<variable>`.

# Specifying normal assignments

```
MODULE main
VAR
  b0 : boolean;
  b1 : boolean;
  out : 0..3;

ASSIGN
  init(b0) := 0;
  next(b0) := !b0;

  init(b1) := 0;
  next(b1) := ((!b0 & b1) | (b0 & !b1));

  out := b0 + 2*b1;
```

## Restrictions on the ASSIGN

---

For technical reasons, the transition relation must be total.

I.e., for every state there must be at least one successor state.

To guarantee that the specified program yields a total transition relation, the following restrictions are applied:

- ➔ Single assignment rule – Each variable may be assigned only once in the program.
- ➔ Circular dependencies rule – A variable cannot have “cycles” in its dependency graph that are not broken by delays.

## Single assignment rule

---

None of the following combinations of assignments is legal:

<code>next(status) := ready;</code> <code>status := ready;</code>	<code>init(status) := ready;</code> <code>status := ready;</code>
<code>init(status) := ready;</code> <code>init(status) := busy;</code>	<code>next(status) := ready;</code> <code>next(status) := busy;</code>
<code>status := ready;</code> <code>status := busy;</code>	

## Circular dependencies rule

---

None of the following combinations of assignments is legal:

<code>x := (x + 1) mod 2;</code>	<code>next(x) := z &amp; next(x);</code>
<code>x := (y + 1) mod 3;</code>	<code>next(x) := x &amp; next(y);</code>
<code>y := (x - 1) mod 3;</code>	<code>next(y) := next(z) &amp; y;</code>
	<code>next(z) := z &amp; next(x);</code>

## The modulo 4 counter with reset

The counter can be reset by an external reset signal.

```

MODULE main
VAR
  b0      : boolean;
  b1      : boolean;
  reset   : boolean;
  out     : 0..3;

ASSIGN
  init(b0) := 0;
  next(b0) := case
    reset = 1 : 0;
    reset = 0 : !b0;
  esac;

  init(b1) := 0;
  next(b1) := case
    reset : 0;
    1     : ((!b0 & b1) | (b0 & !b1));
  esac;

  out := b0 + 2*b1;

```

## Specifying CTL properties

➔ CTL properties are specified via the keyword `SPEC`:

```
SPEC <ctl_expression>
```

➔ It is possible to reach a state in which `out = 3`.

```
SPEC
  EF out = 3
```

➔ A state in which `out = 3` is always reachable.

```
SPEC
  AF out = 3
```

➔ It is always possible to reach a state in which `out = 3`.

```
SPEC
  AG EF out = 3
```

➔ An execution leading to a state in which `out = 3` can be generated with the specification:

```
SPEC
  !EF out = 3
```

# CTL specifications

---

NuSMV provides bounded CTL operators:

☞ There is no state that is reachable in 3 steps where  $\text{out} = 3$  holds.

```
SPEC
  !EBF 0..3 out = 3
```

☞ A state in which  $\text{out} = 3$  is reachable in 2 steps.

```
SPEC
  ABF 0..2 out = 3
```

☞ Invariantly a state in which  $\text{out} = 3$  is reachable in 3 steps.

```
SPEC
  AG ABF 0..3 out = 3
```

## Quantitative characteristics computations

---

- ➡ It is possible to compute the minimum and maximum length of the paths between two specified conditions.
- ➡ For instance, the shortest path between a state in which  $out = 0$  and a state in which  $out = 3$  is computed with

```
COMPUTE  
  MIN [ out = 0 , out = 3 ]
```

- ➡ The length of the longest path between a state in which  $out = 0$  and a state in which  $out = 3$ .

```
COMPUTE  
  MAX [ out = 0 , out = 3 ]
```

## Introducing Fairness Constraints

Let us consider again the counter with reset.

➔ The specification  $\text{AF } \text{out} = 1$  is not verified.

➔ On the path where `reset` is always 1, then the system loops on a state where `out = 0`, since the counter is always reset:

`reset = 1,1,1,1,1,1,1...`

`out = 0,0,0,0,0,0,0...`

➔ Analogous considerations hold for the property  $\text{AF } \text{out} = 2$ . For instance, the sequence:

`reset = 0,1,0,1,0,1,0...`

generates the loop:

`out = 0,1,0,1,0,1,0...`

which is a counterexample to the given formula.

# Fairness Constraints

---

- ➔ NuSMV allows to specify *fairness* constraints.
- ➔ Fairness constraints are CTL formulas which are assumed to be true infinitely often in all the execution paths of interest.
- ➔ During the verification of properties, NuSMV considers path quantifiers to apply only to fair paths.
- ➔ Fairness constraints are specified as follows:

```
FAIRNESS <ctl_expression>
```

# Fairness Constraints

---

With the fairness constraint

```
FAIRNESS
  out = 1
```

we restrict our analysis to paths in which the property  $\text{out} = 1$  is true infinitely often.

The property  $\text{AF } \text{out} = 1$  under this fairness constraint is now verified.

The property  $\text{AF } \text{out} = 2$  is still not verified.

Adding the fairness constraint  $\text{out} = 2$ , then also the property  $\text{AF } \text{out} = 2$  is verified.

## Exercise 1: Mutual Exclusion

---

A two-users mutual exclusion:

- ➡ We have two users `U1` and `U2`, and an Arbiter.
- ➡ Each user can be either `NonCritical`, `Trying` or `Critical`.
- ➡ From `NonCritical`, it can nondeterministically go to `Trying`.
- ➡ From `Trying`, it can go to `Critical` when enabled by the arbiter.
- ➡ From `Critical`, it goes back to `NonCritical` in at most 4 time units.

Design the Arbiter, the users, and ...

- ➡ Verify that the two users cannot be at the same time in their `Critical` section.
- ➡ Verify that if a user tries to enter its critical section, it will eventually succeed.
- ➡ Compute the maximum time needed to enter the critical section.

## Part II: Advanced features of NuSMV

---

## The `DEFINE` declaration

---

- ➡ Defined symbols do not require extra BDD variables creation.
- ➡ Each occurrence of a defined symbol in a specification is replaced with the body of the definition.
- ➡ The BDD corresponding to the body of defined symbols becomes part of each expression using the defined symbol.
- ➡ It is similar to a macro definition.

## The DEFINE declaration

---

```
MODULE main
VAR
  b0 : boolean;
  b1 : boolean;
  b2 : boolean;

ASSIGN
  init(b0) := 0;
  init(b1) := 0;
  init(b2) := 0;

  next(b0) := !b0;
  next(b1) := (!b0 & b1) | (b0 & !b1);
  next(b2) := ((b0 & b1) & !b2) | (!(b0 & b1) & b2);

DEFINE
  out := b0 + 2*b1 + 4*b2;
  reset := b0 & b1 & b2;
```

# Arrays

---

The SMV language provides also the possibility to define arrays of basic data types (and arrays of arrays).

VAR

```
x : array 0..10 of booleans;
```

```
y : array 2..4 of 0..10;
```

```
z : array 0..10 of array 0..5 of {red, green, orange};
```

ASSIGN

```
init(z[3][2]) := {gree, orange};
```

➡ Remark: Array indexes in SMV must be constants.

## Using propositional formulas to specify $M$

The SMV language allows to specify  $M$  using propositional formulas:

```
<init_declaration>      ::- 'INIT' <simple_expr>
<trans_declaration>     ::- 'TRANS' <next_expr>
<invar_declaration>    ::- 'INVAR' <simple_expr>
```

- ➡ No checks performed on these formulas.
- ➡ Logical absurdities can be introduced.
- ➡ Not recommended unless you know what you are doing.
- ➡ Very useful for writing translators from other languages to NuSMV.

## Using propositional formulas to specify $M$

The following SMV program:

```
MODULE main
VAR
  request : boolean;    state   : {ready,busy};
ASSIGN
  init(state) := ready;
  next(state) := case
    state = ready & request : busy;
    1 : {ready,busy};
  esac;
```

is equivalent to:

```
MODULE main
VAR
  request : boolean;    state   : {ready,busy};
INIT
  state = ready
TRANS
  (state = ready & request) -> next(state) = busy
```

# Modules

---

- ➔ Modules in SMV are a bundle of definitions that can be reused.
- ➔ Modules are composed by instantiating them inside another module.
- ➔ Instantiation is performed inside the `VAR` declaration of a module.
- ➔ They can have *formal parameters*, which are substituted with the actual parameters when the module is instantiated.
- ➔ Actual parameters can be any legal expression.
- ➔ The semantic of module instantiation and parameters passing is similar to call-by-reference.
- ➔ All the variables of an instance of a module can be passed to another module by passing the module instance name as argument.

## Example: The modulo 8 counter revisited

---

```
MODULE counter_cell(tick)
```

```
VAR
```

```
  value : boolean;
```

```
ASSIGN
```

```
  init(value) := 0;
```

```
  next(value) := case
```

```
    tick = 0 : value;
```

```
    tick = 1 : (value + 1) mod 2;
```

```
  esac;
```

```
DEFINE
```

```
  done := tick & (((value + 1) mod 2) = 0);
```

`tick` is the formal parameter of module `counter_cell`.

## Example: The modulo 8 counter revisited

---

Module `counter_cell` is instantiated three times.

```
MODULE main
  VAR
    bit0 : counter_cell(1);
    bit1 : counter_cell(bit0.done);
    bit2 : counter_cell(bit1.done);
    out  : 0..7;

  ASSIGN
    out := bit0.value + 2*bit1.value + 4*bit2.value;
```

In the instance `bit0`, the formal parameter `tick` is replaced with the actual parameter `1`.

When a module is instantiated all variables/symbols defined in it are preceeded by the module instance name, so that they are unique to the instance.

## Restriction on MODULE declaration

---

- ➡ There must be a module `main` in a SMV specification.
- ➡ The module `main` has a special meaning in the SMV language, in the same way that it does in the C programming language.
- ➡ There must be no recursively defined modules.
- ➡ You cannot instantiate with the same name two modules.
- ➡ All the variables declared in a module instance are visible in the module in which it has been instantiated via the dot notation.

## Module hierarchies

---

A module can contain instances of others modules provided the module references are not circular.

```
MODULE counter_8 (tick)
  VAR
    bit0 : counter_cell(tick);
    bit1 : counter_cell(bit0.done);
    bit2 : counter_cell(bit1.done);
    out  : 0..7;

  DEFINE
    done := bit2.done;

  ASSIGN
    out := bit0.value + 2*bit1.value + 4*bit2.value;
```

## Module hierarchies (cont.)

---

```
-- A counter modulo 512

MODULE main
  VAR
    b0 : counter_8(1);
    b1 : counter_8(b0.done);
    b2 : counter_8(b1.done);
    out : 0..511;

  ASSIGN
    out := b0.out + 8*b1.out + 64*b2.out;

  SPEC
    AF b2.bit2.done

  SPEC
    !EF out = 511
```

## Exercise 2

---

Use modules and arrays to

- Extend the mutual exclusion controller of exercise 1 to a generic number of users.
- Implement the read-write lock algorithm described below:

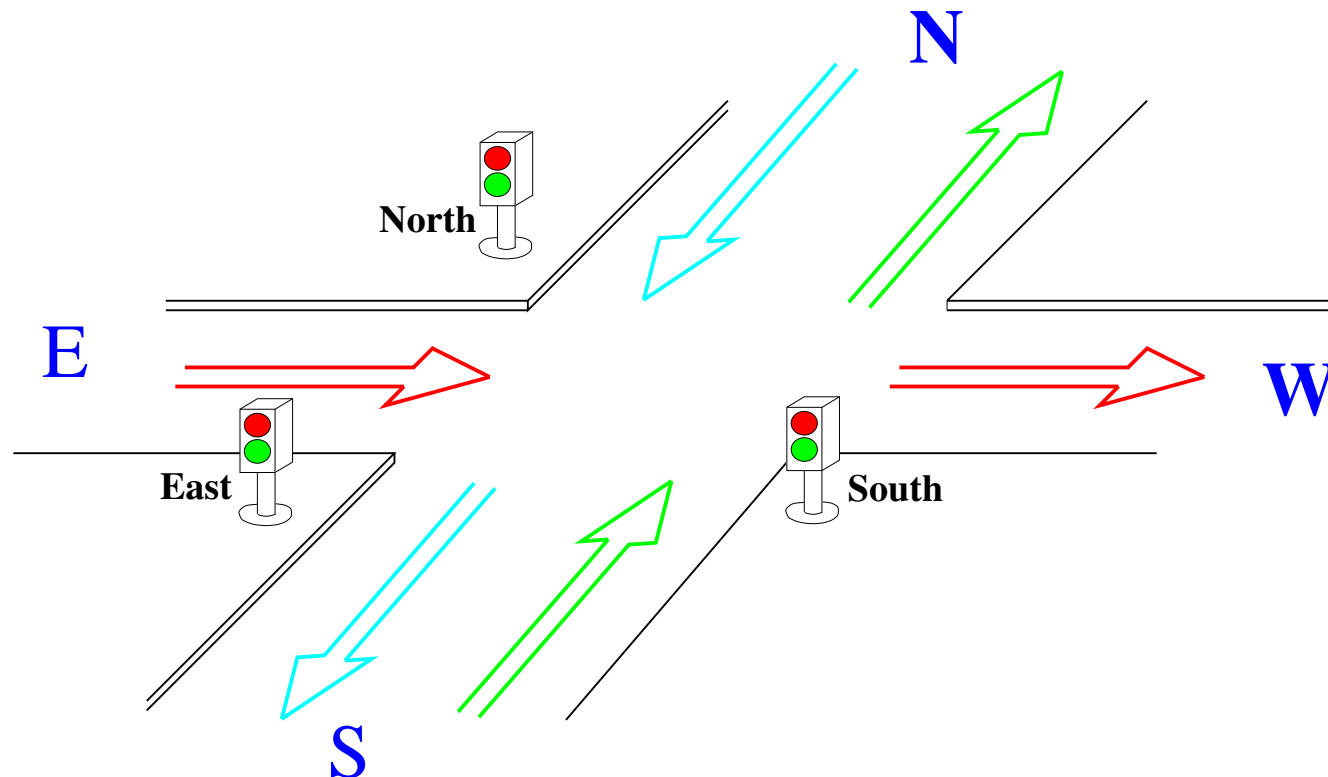

A Readers/Writer lock controls the access to a resource (for instance a cache memory) that can be read simultaneously by many users, but that can be written only by a user that has an exclusive access.

In any moment the resource can be:

- either unused,
- or accessed in read mode by one or more users,
- or accessed in read-write mode by an exclusive user.

## Exercise 3

Design a traffic lights controller of an intersection where a two-way street running north and south intersects a one way street running West, such that collisions are avoided and cars do not wait forever at red light.

## Exercise 3 – hints

---

- ➡ We need a sensor for each direction to indicate the presence of a car in that direction. It can be considered an input to the system.
- ➡ We need for each direction a variable to indicate the color of the light.
- ➡ We need a lock that is set when the traffic is enabled in North-South directions, and prevents East light to become green.
- ➡ We need a boolean variable for each direction to remember if there has been or not a request.

## Partitioning the transition relation

---

The basic computation in symbolic model checking is the relational product:

$$S(\underline{x}') = \exists \underline{x}. (S(\underline{x}) \wedge R(\underline{x}, \underline{x}'))$$

- ☞ There are efficient algorithms for computing  $S(\underline{x}')$ , without building the conjunction, but ...
  - operation is complex;
  - monolithic  $R$  sometimes is too large;
- ☞ Avoid building  $R$  by partitioning.

## Conjunctive Partitioning

Represent  $R$  as an implicitly conjoined list of smaller transition relation.

$$R(\underline{x}, \underline{x}') = \bigwedge_{i=0}^n R_i(\underline{x}, \underline{x}')$$

and thus perform early quantification:

$$\begin{aligned}
 S(\underline{x}') &= \exists \underline{x}. (S(\underline{x}) \wedge R(\underline{x}, \underline{x}')) && = \\
 &= \exists \underline{x}. (S(\underline{x}) \wedge \bigwedge_{i=0}^n R_i(\underline{x}, \underline{x}')) && = \\
 &= \exists \underline{x}_n (\dots \exists \underline{x}_1 \underbrace{(\exists \underline{x}_0 (S(\underline{x}) \wedge R_0(\underline{x}, \underline{x}')) \wedge R_1(\underline{x}, \underline{x}'))}_{S_0} \dots \wedge R_n(\underline{x}, \underline{x}')) \\
 &\quad \underbrace{\hspace{10em}}_{S_1} \\
 &\quad \underbrace{\hspace{15em}}_{S_n}
 \end{aligned}$$

# Conjunctive partitioning in NuSMV

---

NuSMV provides two conjunctive partitioning heuristics.

- ➔ Conjunctive partitioning in NuSMV is actually only available for synchronous systems.
- ➔ Individual **next()** assignments are grouped into partitions whose size in terms of BDD nodes does not exceed a given threshold.
- ➔ A refinement of the above. Individual **next()** assignments are grouped into partitions whose size in terms of BDD nodes does not exceed a given threshold. Then the partitions are ordered according to an heuristic in order to improve image computation efficiency [RAP<sup>+</sup>95].

## Variable Ordering

- ➔ NuSMV uses BDDs to encode states.
- ➔ The order of the variables can have a big impact on the size of the BDD (for a given formula) and thus on the performances.

$$(A \leftrightarrow B) \wedge (C \leftrightarrow D)$$

A, B, C, D

A, C, B, D

## Variable Ordering

The default ordering used by NuSMV is the order in which the variables are declared in a depth-first traversal of the module hierarchy starting from the module `main`.

```
MODULE counter_cell(tick)
VAR
  value : boolean;
ASSIGN
  init(value) := 0;
  next(value) := case
    tick = 0 : value;
    tick = 1 : (value + 1) mod 2;
  esac;
DEFINE
  done := tick & (((value + 1) mod 2) = 0);

MODULE main
VAR
  bit0 : counter_cell(1);
  bit1 : counter_cell(bit0.done);
  bit2 : counter_cell(bit1.done);
  out : 0..7;
ASSIGN
  out := bit0.value + 2*bit1.value + 4*bit2.value;
```

The default ordering is: `bit0.value`, `bit1.value`, `bit2.value`, `out`

# Variables Ordering

---

- ➔ NuSMV allows the user to specify the order of the variables.
- ➔ A “good” variable order can be specified by hand or generated automatically by automatic variable reordering algorithms (NuSMV provides 19 different algorithms).
- ➔ If in the previous example we use the variable ordering:

```
bit0.value, out, bit1.value, bit2.value
```

The the size of the transition relation changes from 32 BDD nodes to 23 BDD nodes.
